## 1 BACKGROUND OF THE INVENTION

2  
3 The present invention relates to Digital Television (DTV) in general and specifically  
4 to the Advanced Television Systems Committee (ATSC) standard for terrestrial broadcast  
5 television in the United States.

6 The ATSC DTV standard was determined by the "Grand Alliance" and subsequently  
7 accepted by the broadcast community, the consumer electronics industry and the  
8 regulatory infrastructure. The regulatory infrastructure has mandated a strictly scheduled  
9 transition for the transition of terrestrial broadcast television in the United States from the  
10 National Television System Committee ("NTSC" or "analog") standard to the ATSC  
11 ("digital") standard. At the time of this disclosure, a significant investment is in place, on  
12 behalf of the broadcast industry, in terms of substantial progress in cooperation with the  
13 planned transition. Similarly, many consumers have purchased ATSC television receiver  
14 equipment in the form of new ATSC-system compliant DTV television sets and in the  
15 form of DTV television set-top converters.

16 However, the ATSC standard, in its present form, is deficient in its susceptibility to  
17 multipath. It is well known that in side-by-side comparisons, ATSC (new digital system)  
18 reception is often inferior to NTSC (conventional analog system) reception.  
19 Additionally, ATSC mobile reception is observed to suffer more substantial degradation  
20 due to multipath than NTSC mobile reception. It is also well known that signal strength  
21 and signal-to-noise ratio (SNR) are not at issue. Unanticipated inferior reception  
22 manifests itself at high levels of received signal power and at high receiver signal-to-

1 noise ratios (SNR's). This fact, coupled with spectral analysis of received ATSC DTV  
2 signals, point directly to multipath as the cause of inferior reception.

3 Various inventors have disclosed significant work in the area of DTV reception.  
4 Included in this work is Park et al. in 5,592,235, issued January 7, 1997, which describes  
5 means of efficiently combining reception, appropriate to terrestrial broadcast and to cable  
6 broadcast, both in a single receiver. Also included in this work is Oshima in 5,802,241,  
7 issued September 1, 1998, which describes a plurality of modulation components  
8 modulated by a plurality of signal components.

9 The use of decision-feedback equalizers (DFE) in digital demodulation is a matter of  
10 prior art. Unfortunately, DFE equalization is not suitable for enabling the initial  
11 acquisition of digital modulation severely distorted by multipath-induced intersymbol  
12 interference. For this purpose, a reference waveform or reference sequence is typically  
13 introduced. The use of a reference sequence equalizer is considered by Lee in 5,886,748,  
14 issued March 23, 1999, which describes in very general terms the use of a reference  
15 sequence for equalizing "GA-HDTV" signals. Unfortunately, the cited work does not  
16 address the multipath issues relevant to ATSC DTV reception. Neither does this work  
17 address the compatibility between the referenced "training sequence" with the existing  
18 ATSC DTV standard. Nor does the cited work address the relevance or appropriateness  
19 of the referenced training sequence and equalization method to VHF and UHF multipath,  
20 whose impact on ATSC DTV reception was discovered after the fact of the cited work.

21 Also of importance to the present introduction of terrestrial ATSC DTV in the United  
22 States is the work by Limberg in 5,923,378, issued July 13, 1999. This work addresses

## BRIEF SUMMARY OF THE INVENTION

The present invention addresses the strategy of enabling "reference" or "training" "sequence" or "waveform" equalization by introducing an equalizer training waveform compatibly with the present ATSC DTV standard for terrestrial broadcast DTV in the United States. A training waveform is induced into the ATSC DTV modulation waveform by introducing training sequence placeholders onto the ATSC DTV multiplex and transport. Subsequent processing yields modulation training suitable for allowing and tailored to enabling the adaptive equalization processes required at the receiver to address VHF and UHF multipath. The necessary transmission signal processing is accomplished with no hostile effects in terms of backward compatibility with pre-existing legacy ATSC DTV receivers. The training waveform as such is induced specifically to enable training-waveform-based equalization adequate and necessary to address multipath-induced intersymbol interference otherwise known to be catastrophic to ATSC DTV reception.

ATSC DTV modulation is preserved and ATSC DTV multiplex and transport remain compatible with the existing ATSC DTV standard. As such, the existing ATSC DTV infrastructure is compatible with the disclosed ATSC DTV multipath solution. Every existing ATSC DTV receiver continues to function as it has functioned before. Retrofit of preexisting consumer ATSC DTV receiver equipment is unnecessary. However, the production of new consumer ATSC DTV receiver equipment is made possible, through this disclosure, with minimum economic disruption. The practical cost and complexity of

1 the necessary transmission equipment upgrade is minimized through the exploitation of  
2 the backwards-compatible ATSC DTV multiplex and transport training sequence  
3 induction technique disclosed. Substantial and significant advantage with respect to  
4 multipath equalization processing is enabled through the exploitation of the backward  
5 compatible ATSC DTV modulation and transmission training waveform induction  
6 technique disclosed.

## 1 DETAILED DESCRIPTION OF THE INVENTION

2  
3 The ATSC DTV transmission system is illustrated in Fig. 1. The transmission system  
4 multiplexes 125 various components of the broadcast program, including video 105,  
5 audio 110, data 115 and control information 120. The service multiplex stream 130 is  
6 randomized 135, Reed-Solomon encoded 140, byte-interleaved 145 and TCM encoded  
7 150 in preparation for modulation. Modulation consists of the introduction 165 of  
8 segment sync 155 and field sync 160, addition of a pilot 170, followed by  
9 preequalization 175, VSB modulation 180 and RF upconversion 185. The modulation  
10 format is commonly described in terms of the "ATSC DTV modulation frame" illustrated  
11 in Fig. 2.  
12

13 The foremost weakness of the ATSC DTV standard for terrestrial broadcast digital  
14 television is its susceptibility to multipath. Fig. 3 illustrates the dilemma caused by  
15 multipath. The propagation path from the broadcast transmitter site 310 to any given  
16 receiver sight ("NTSC" 380 or "DTV" 390) may involve any whole number (zero or  
17 more) of propagation paths 320, 330, 340, 350, 360 and 370. Each independent or unique  
18 propagation path 320, 330, 340, 350, 360 and 370 has independent or unique amplitude,  
19 delay and phase characteristics. The customary consumer antenna does not distinguish  
20 from multiple paths. Such a process (multiple antennas or phased arrays) is beyond the  
21 capability of conventional consumer electronic equipment customary for use in television  
22 reception. Consequently, each received signal from each of multiple paths 320, 330, 340,

1 350, 360 and 370 contributes either constructively or destructively to each other received  
2 signal from each other associated path 320, 330, 340, 350, 360 and 370. It is more likely  
3 that two or more multiple paths 320, 330, 340, 350, 360 and 370 add destructively rather  
4 than constructively. The complication of multiple additive amplitude, phase and delay  
5 responses yields a received signal subject to unpredictable linear time and frequency  
6 distortion or self-interference.

7  
8 Again in Fig. 3, on the right side of the figure, an NTSC (conventional analog)  
9 receiver 380 is shown above and a DTV (ATSC standard digital) receiver 390 is shown  
10 below. This aspect of Fig. 3 serves to illustrate the present dilemma faced by the  
11 broadcast industry. In the case of the conventional analog "NTSC" system 380 depicted  
12 above, multipath manifests itself in terms of analog interference. The resulting program  
13 distortion manifests itself primarily as "ghosting." "Ghosts" of the analog image consist  
14 of superimposed copies of the intended picture appearing over the intended picture in the  
15 video display. Ghosts are commonly observed in terrestrially received NTSC video  
16 images. This video image ghosting is sometimes tolerable to the viewer, as ghosting may  
17 or may not be substantially significant in terms of image degradation. This is in contrast  
18 to the multipath distortion effects commonly observed in new digital "ATSC" 390 DTV  
19 reception described. With respect to the ATSC modulation waveform, multipath  
20 manifests itself in intersymbol interference. Intersymbol interference is known, in the  
21 ATSC system, to cause catastrophic failure. There is no "ghosting" or "graceful  
22 degradation." The signal is simply lost (SNR "cliff effect") or it is never acquired (when

intersymbol interference violates demodulation signal acquisition thresholds). In the former case, the visible result is image "freezing" or "deresolution" due to loss of data. In the former case, the audible result is muting (loss of audio). In the latter case, the visible result is a blank screen and silent audio. Based on these observations, and on their corresponding frequency of occurrence, one skilled in the art of television reception arrives at the conclusion that the ATSC DTV standard format, in its present form, constitutes a service downgrade with respect to reception reliability.

Multipath may be modeled in continuous time as a linear convolutional process  $h(t, \tau)$  440 as shown in Fig. 4. In this figure, the symbol sequence  $x(n)$  410 is applied to the modulator 420, producing a modulation waveform  $s(t)$  430. The propagation channel is represented by the convolutional process  $h(t, \tau)$  440 and the additive 470 noise process  $n(t)$  460. The resulting signal  $r(t)$  480 is received at the ATSC DTV receiver.

The modulation and channel propagation processes lend themselves to time-sampled representation as shown in Fig. 5. In this figure, the modulation signal  $s(n)$  530 is modeled as a time-sampled waveform in time index  $n$ . Although the same time index is used for the symbol sequence  $x(n)$  410, it is important to note that "N  $\times$  sampling" ("N-times sampling") is common to digital signal processing relevant to both the transmission and reception systems. The use of the same time index for both waveforms is not intended to preclude the use of "N  $\times$  sampling" in this application. The modulation

1 symbol sequence  $x(n)$  410 in time index  $n$  is to be thought of as adhering to the  
2 identical " $N \times$  sampling" process and consisting of repeated sets of " $N-1$ " "zero" samples  
3 interspersed with single symbol states.  
4

5 Nor should the absence of complex notation throughout this application be  
6 misconstrued as to preclude the use of complex sampling. Complex sampling is both  
7 anticipated and expected, omitted in this application merely for the sake of simplifying  
8 the disclosure.  
9

10 In Fig. 5, the same linear convolutional multipath response  $h(t, \tau)$  440 is modeled as  
11 a time-sampled vector process  $\bar{h}(n, m)$  540 where  $n$  is the time index and  $m$  is the time-  
12 response index, indicating a "vector" sampled-time response in  $m$  at every time sample  
13  $n$ . Lastly, channel noise  $\mathbf{n}(n)$  560 is added 570 on a sample-by-sample basis to yield the  
14 received time-sampled waveform  $r(n)$  580.  
15

16 This time-sampled model is applied to the drawings, which illustrate prior art applied  
17 to ATSC DTV equalization. Fig. 6 illustrates a blind equalizer used to adaptively  
18 converge 650 on a sufficiently accurate approximation  $\hat{\bar{h}}^{-1}(n, m)$  610 of the inverse  
19  $\bar{h}^{-1}(n, m)$  of the channel response  $\bar{h}(n, m)$  540. Fig. 7 illustrates the decision feedback  
20 equalizer applied to the same purpose. A training waveform equalizer is illustrated in  
21 Fig. 8. In all cases, prior art has failed to produce a suitable equalizer and/or demodulator

1 capable of reliably receiving the conventional ATSC DTV terrestrial broadcast waveform  
2 in the presence of significant multipath.

3

4 An inherent weakness of the ATSC DTV standard system, illustrated in the simplified  
5 block diagram of Fig. 9, is the 24.2 ms interval 220 between successive training  
6 waveforms 160 in the modulation frame, illustrated in Fig. 2. This training waveform  
7 interval 220 is not short enough to enable receivers to accurately track temporal multipath  
8 variations quickly enough to yield effective reception. One possible solution is to  
9 explicitly introduce additional training waveform components 160 more frequently into  
10 the modulation frame. The required system modifications are illustrated in Fig. 10. Such  
11 a solution would be politically detrimental in that it would render existing ATSC DTV  
12 transmission and reception equipment obsolete. As such, the direct addition of  
13 supplemental training waveform components is economically untenable.

14

15 An economically viable solution requires "backward compatibility" with existing  
16 receivers. Such a solution may be identified by the following marks.

17

- 18 1. Enables continuous reliable viewing in the presence of significant multipath  
19 channel impairments

20

1           2. "Significant multipath channel impairments" to include "ghosts" generated by  
2           reflections and/or obstructions moving at 100 kilometers per hour (> 60 MPH)  
3           with respect to reception equipment  
4

5           3. This while every preexisting legacy ATSC DTV receiver  
6

7           a) receives the same signal  
8

9           b) to the extent that it can be received in the absence of any transmission  
10          waveform modifications  
11

12          The present invention consists of a method of introducing new, more frequent  
13          training symbols into the modulation frame through backward compatible induction. Fig.  
14          11 illustrates the necessary modifications to the ATSC DTV transmission and reception  
15          systems. In this method, "supplemental training sequence" data **1110** is introduced into  
16          the service multiplex **125** in the form of periodic packets **1110**. Such packets are formed  
17          with the ATSC DTV standard in mind in such a manner as to induce frequent and  
18          advantageous training symbol components **1120** into the ATSC DTV modulation frame  
19          illustrated in Fig. 2.  
20

21          The operation of the training symbol induction method is best described by example.  
22          In the first example, one training symbol packet is introduced into the service multiplex

after every 12 conventional MPEG-2 service multiplex packet. The effective service rate is reduced by  $\frac{1}{13} \cong 8\%$  in the interest of inducing the advantageous frequent training symbol components. Fig. 12 emphasizes the introduction of the training symbol packet data 1110 and the subsequent interleave processing 145, inherent to ATSC-DTV standard transmission, which has the effect of distributing the induced training symbols throughout the modulation frame illustrated in Fig. 2. Fig. 13 illustrates the sequence of new supplemental training symbol packets 1110 and conventional MPEG-2 multiplex packets 1310 at the output of the service multiplexer 125. Fig. 14 illustrates the interleave process 145 i.a.w. the ATSC DTV standard.

The distribution of MPEG-2 training symbol bytes by the interleaver 145 in the modulation frame (Fig. 2) is illustrated in Fig. 15 using an example where 1 training sequence packet is introduced per 5 conventional MPEG-2 data packets, or 6 total MPEG-2 packets. In this illustration, every box represents a byte of multiplexed data read left-to-right, then top-to-bottom. The numbered boxes indicate the positions of the post-interleave training symbol bytes i.a.w. the ATSC DTV standard byte interleave process 145. In this manner, each byte of each training sequence packet 1110 in the service multiplex 125 is mapped through the interleave process 145. Not shown is the addition 140 of Reed-Solomon (R/S) checkbytes to each service multiplex packet i.a.w. ATSC-DTV standard transmission practice.

1 Subsequent ATSC-DTV standard processing is required before corresponding new  
2 supplemental training symbols **1120** are manifested into the DTV modulation frame (Fig.  
3 2). The byte-interleaved service multiplex, which is the output of the byte interleaver  
4 **145**, is applied to a TCM (trellis-coded modulation) byte interleaver as shown in Fig. 16.  
5 Each of the 12 parallel TCM encode processes **1650** involve bit interleaving as shown in  
6 Fig. 17 and TCM encoding as shown in Fig. 18. In the induction method disclosed, each  
7 induction data bit is mapped from the interleaved service multiplex data stream (output of  
8 byte interleaver **145**) to the modulation frame (per ATSC Standard as illustrated in Fig. 2)  
9 in the same manner that the induction data packet bytes were mapped through the R/S  
10 encode process and subsequent byte interleave process into the interleaved service  
11 multiplex data stream (in the manner of Fig. 15).

12  
13 The essence of this method is the exploitation of this mapping to induce frequent  
14 regular periodic training symbol components into the modulation frame so as to enable  
15 effective multipath reception at the compatible receiver while maintaining backwards-  
16 compatibility with pre-existing legacy reception equipment.

17  
18 It is important that the training symbol components induced into the ATSC DTV  
19 modulation frame be of sufficient number and frequency as to enable effective multipath  
20 reception. Such frequency and number is determined by evaluating relevant propagation  
21 parameters.

22

1 The first relevant propagation parameter is the multipath delay spread. The relevant  
2 VHF and UHF multipath delay spreads are on the order of up to 100  $\mu$ s. Another  
3 relevant propagation parameter is the highest transmission frequency. This frequency  
4  $f_{\max}$  corresponds to the highest terrestrial broadcast television channel,

5

6 
$$f_{\max} \cong 800 \text{ MHz}$$

7

8 The minimum transmission wavelength  $\lambda_{\min}$  is computed from the highest  
9 transmission frequency  $f_{\max}$  using

10

$$\begin{aligned}\lambda_{\min} &\cong \frac{c}{f_{\max}} \\ &\cong \frac{3 \times 10^8}{800 \times 10^6} \\ &\cong .375 \text{ m}\end{aligned}$$

11

12

13 The maximum multipath reflection component velocity  $v_{\max}$  is calculated in terms of  
14 maximum number of wavelengths per second from the 100 kph benchmark as follows.

15

$$v_{\max} \cong 2 \times 100 \text{ kph} \cong 200 \text{ kph}$$

$$\begin{aligned} &\cong 200 \text{ kph} \times \frac{1000 \text{ m}}{\text{km}} \times \frac{1 \text{ hr}}{3600 \text{ s}} \times \frac{\lambda_{\min}}{.375 \text{ m}} \\ &\cong 150 \frac{\lambda_{\min}}{\text{s}} \end{aligned}$$

2

3 The corresponding minimum multipath-ray phase-change or phase-rotation  
4 periodicity  $T_{\text{reflection}}$  is calculated from this  $v_{\max}$  using

5

$$\begin{aligned} T_{\text{reflection}} &\cong \frac{1}{150} \\ &\cong \frac{7 \text{ ms}}{\lambda_{\min}} \end{aligned}$$

7

8 Finally, experience indicates the prudence of offering provisions for updating  
9 multipath equalizers more than 10 times per minimum path variation cycle interval.  
10 Using instead a more conservative factor of 20, the recommended equalizer update  
11 interval is calculated to be

12

$$\begin{aligned} T_{\text{update}} &\cong \frac{7 \text{ ms}}{\lambda_{\min}} \times \frac{\lambda_{\min}}{20 \text{ updates}} \\ &< 350 \mu\text{s} \end{aligned}$$

14

15 or

1

2  $T_{update} < 350 \mu s$

3

4

5 In summary, adequate ATSC DTV multipath equalization calls for equalization of

6 delay spreads on the order of up to 100  $\mu s$  at update intervals of less than 350  $\mu s$ .

7

8 The preferred embodiment is derived from

- 9 1. the need to introduce training waveforms at intervals of less than 350  $\mu s$
- 10 so that associated receivers can successfully track multipath using reliable
- 11 reference-trained equalizers
- 12 2. the need to supply sufficient training symbols in each such training
- 13 waveform so as to ensure the ability of trained equalizers to sufficiently
- 14 train at the intervals indicated
- 15 3. the need to match training waveform periodicity with those of the pre-
- 16 existing ATSC Standard
- 17 4. the need to keep the enhancement simple
- 18 5. the need to restrict the introduction of training symbols to a reasonably
- 19 small percentage of the system data throughput so as to preserve
- 20 information capacity
- 21

1 The preferred embodiment consists of the introduction of 4 induction packets per 52  
2 multiplex packets. Periodicity is essential, as it is essential that the receiver be able to  
3 find the induced reference symbols. A periodicity of 52 multiplex packets is chosen  
4 because 52 multiplex packets divides evenly into the 624 multiplex packets which map  
5 into the ATSC DTV modulation frame and into the 12-branch TCM encode interleave  
6 process i.a.w. the ATSC DTV standard ( $52 \times 12 = 624$ ).

7  
8 In the preferred embodiment, 4 induction packets per 52 service multiplex packets  
9 map into approximately 96 full training symbols per 3 modulation segments (232  $\mu$ s) plus  
10 96 partial training symbols. These second 96 "partial" training symbols are "partial" in  
11 the sense that their state cannot be fully controlled due to the two-bit delay 1820 inherent  
12 in the ATSC-DTV standard TCM encoding process, illustrated in Fig. 18. Their state  
13 may only be partially controlled in the sense that the bit which is not subject to  
14 convolutional coding delay is used to map the major component of the symbol state as  
15 opposed to the entire symbol state. The relevant correlation processing gain is  
16 approximated using

$$10 \log(96 \times 1.5) > 20 \text{ dB}$$

17  
18  
19  
20 offering greater than 20 dB processing gain with which to resolve the channel response.

21

1 As such, the preferred embodiment offers adequate and sufficiently frequent means to  
2 characterize multipath suitably for reliable ATSC DTV receiver channel characterization  
3 and demodulation, or to otherwise serve as a reference against which to train the  
4 corresponding equalizers.

5  
6 Also crucial to the successful implementation of the training symbol induction  
7 method is the necessity to ensure compatibility of the induction packets with existing  
8 receivers. It is necessary that preexisting legacy receivers "reject" such packets. This is  
9 accomplished through one or both of the following techniques:

- 10  
11 1. The induction process verifies or causes training symbol induction packets  
12 to be invalid and "uncorrectable" R/S codewords (distance > 10 R/S  
13 characters to nearest valid codeword) so as to be discarded by the receiver  
14  
15 2. The induction process causes training symbol induction packets to be  
16 associated with an unused MPEG-2 program channel so as to be discarded  
17 by the receiver  
18

19 The data overhead associated with either of these processes does not cause an  
20 appreciable degradation to the > 20 dB processing gain associated with the preferred  
21 embodiment described above.

22

1 Of significance to the method disclosed is the fact that induced training symbols do  
2 not typically appear contiguously in the modulation frame, but are instead typically  
3 interspersed between data symbols. The result is that a longer time base is used to  
4 formulate each channel multipath approximation.

5  
6 The preferred embodiment at the receiver is to employ a reference-trained equalizer  
7 such as the one illustrated in Fig. 8. Such an equalizer would exploit the sufficiently  
8 frequent training waveform and the a-priori knowledge of training symbol locations to  
9 find the training symbols and to train the equalizer against them. Measures to acquire  
10 and maintain symbol and modulation frame timing would be required.

11  
12 An alternative reception method involves

- 13  
14 1. Use of a correlator to determine a sufficiently accurate approximation  $\hat{h}(n,m)$  for  
15 the multipath channel response  $\bar{h}(n,m)$  540 at every training waveform interval  
16  
17 2. Use of an LMS, RLS or other relevant technique to approximate the necessary  
18 inverse-channel function  $\bar{h}^{-1}(n,m)$  610 required in the implementation of the  
19 required equalizer  $\hat{\bar{h}^{-1}}(n,m)$  610  
20

1 In terms of the correlator, an objection may be raised in terms of anticipated  
2 complexity. However, a very computationally efficient correlator is constructed as  
3 follows.

4  
5 1. Whereas ATSC-DTV 8-VSB symbol states (-7, -5, -3, -1, 1, 3, 5 and 7) are offset  
6 i.a.w. the ATSC DTV standard by a pilot of magnitude "1.25," the effective  
7 symbol states become (-5.75, -3.75, -1.75, 0.25, 2.25, 4.25, 6.25 and 8.25)

8  
9 2. A reasonable and acceptable approximation to these states are the states (-6, -4, -  
10 2, 0, 2, 4, 6 and 8)

11  
12 3. Correlation of a  $96 \times 2 = 192$  symbol sequence involves 192 multiplies per point,  
13 which is *extremely* computationally intensive. However, the required multiplies,  
14 subject to the approximation above, may instead be implemented in fixed-point  
15 arithmetic using successive bit-shifts and adds (i.e. multiplication by 4 is a 2-bit  
16 shift; multiplication by 6 is the sum of the results of a 1-bit shift and a 2-bit shift).  
17 The resulting implementation significantly reduces computational burden.

18  
19 4. A minor modification of the ATSC DTV standard consisting of a change in the  
20 pilot level from 1.25 to 1 renders the above approximation (step 2) exact

21

1       The preferred reception method involves the use of the correlator described above to  
2   acquire and maintain symbol and frame timing while employing the reference-trained  
3   equalization process of Fig. 8 to suppress multipath-induced intersymbol interference.
